| This report presents a simplified design method for riprap sizing that allows adjustment of riprap size for specified safety factor, bend placement, side slope placement, specific weight, stone shape, channel shape effects, and roughness effects. It presents design nomographs for each of four sizing methods: Isbash, tractive force-logarithmic profile, tractive force-power profile, and Froude method. Method differences and advantages are explored. This report also discusses various practical riprap design considerations including transition design, strip roughness, and flow types. Examples are included.  20. DISTRIBUTION/AVAILABILITY OF ABSTRACT  21. SECURITY CLASSIFICATION OF THIS PAGE

#### **PREFACE**

The work described herein was performed by Mr. A. J. Reese, formerly of the Design Criteria Branch, Hydraulic Analysis Division, Hydraulics Laboratory, US Army Engineer Waterways Experiment Station (WES), with funding provided by the US Army Corps of Engineers through Work Unit No. 31158, Collection, Analysis, and Dissemination of Hydraulic Design Criteria Procedures, of the Flood Control Hydraulics Research Program.

This study was performed under the direction of Messrs. H. B. Simmons and F. A. Herrmann, Jr., former and present Chiefs of the Hydraulics Laboratory; Mr. M. B. Boyd, Chief of the Hydraulic Analysis Division; and Mr. B. J. Brown, Chief of the Design Criteria Branch. This report was edited by Mrs. Marsha C. Gay, Information Technology Laboratory.

Special acknowledgement is given to Messrs. J. L. Grace, Jr., former Chief, Hydraulic Structures Division; N. R. Oswalt, Chief, Spillways and Channels Branch; and S. T. Maynord, Spillways and Channels Branch, for their assistance and critical review during the preparation of this document.

COL Dwayne G. Lee, CE, is the Commander and Director of WES. Dr. Robert W. Whalin is the Technical Director.

#### NOMOGRAPHIC RIPRAP DESIGN

#### PART I: DEVELOPMENT

#### Introduction

1. This report presents a nomographic solution procedure for the design of riprap. The procedure incorporates five different riprap design methods and adjusts riprap size for (a) specified safety factor, (b) bend placement, (c) side slope placement, (d) a range of riprap specific weights, (e) stone shape, (f) use of hydraulic radius or local depth, and (g) specified roughness size. Examples are presented to illustrate the use of the nomographs.

#### Background

2. The development of the five methods of riprap design is presented in detail elsewhere (Reese 1984) and will only be summarized here.

#### Isbash method

3. By summing the forces on a stone, Isbash (1932, 1936) arrived at an equation which, presented in dimensionless form, is

$$\frac{\rho U_b^2}{(\gamma_s - \gamma) d_{50}} = 2K_I^2 \tag{I}$$

where

o = mass density of water\*

 $U_h = velocity on the stone$ 

Y = specific weight of stone

Y = specific weight of water

 $d_{50}$  = median stone diameter

 $K_T$  = empirical constant

<sup>\*</sup> For convenience, symbols and abbreviations are listed in the Notation (Appendix A).

4. In areas where no velocity profile has been developed (e.g., below a structure), mean channel velocity V is commonly substituted for  $U_{\hat{b}}$ . The value of  $K_{\hat{I}}$  is generally taken as 0.86 for high turbulence locations and 1.2 for low turbulence locations (Office, Chief of Engineers (OCE), US Army, 1970).

#### Tractive force-logarithmic profile

5. The average boundary shear stress can be approximated by the following equation (OCE 1970)

$$\bar{\tau}_{0} = \frac{\gamma V^{2}}{\left(32.6 \log_{10} \frac{12.2 \text{pD'}}{k_{s}}\right)^{2}}$$
 (2)

where

 $\bar{\tau}_{o}$  = average boundary shear, 1b/ft<sup>2</sup>

p = multiple of depth such that hydraulic radius R = pD'

D' = depth to a fixed datum, ft

 $k_{g}$  = equivalent sand grain roughness of boundary, ft

- 6. This profile was originally derived using hydraulic radius R instead of depth D' (Keulegan 1938). Hydraulic radius, when used with mean channel velocity, accounts somewhat for the channel shape effects. Hydraulic radius is replaced by a multiple of depth (i.e., R = pD', see Plate 11) in this and later equations. The value of p is taken equal to 1 when local mean depth is used with the corresponding mean velocity in the vertical  $\bar{v}$  to approximate shear at a point  $(\bar{\tau}_0)$ . For all irregularly shaped cross sections it is recommended that local mean velocity above the stone be estimated and used instead of mean channel velocity. See Table 1 for further details.
- 7. Depth D' is measured from the free surface down to the assumed origin of the logarithmic profile. The original tractive force-logarithmic profile (OTFL) assumed depth to top of stone D for D' and  $d_{50}$  for  $k_{\rm S}$  (OCE 1970). Evidence exists that the actual origin of the profile may be about  $d_{50}$  below the top of the rock layer and that  $k_{\rm S}$  is somewhat greater than  $d_{50}$ . Using known riprap roughness measurements,  $k_{\rm S}$  can be shown to be about  $3d_{50}$  (although the value probably varies with depth, gradation, and shape) (Reese 1984, Rey 1979). D will be used for D' throughout the remainder of this report.

# Modified tractive force-logarithmic profile

8. A modified profile (MTFL) can be developed for calculation purposes as

$$\bar{\tau}_{o} = \frac{\gamma v^{2}}{\left[32.6 \log_{10} \frac{12.2p}{m} \left(\frac{D}{d_{50}} + 1\right)\right]^{2}}$$
 (3)

where m is an empirical multiplier as

$$k_s = md_{50} \tag{4}$$

Again, for local mean velocity p = l and local depth is used.

9. The critical tractive force is

$$\tau_c = K_T (\gamma_s - \gamma) d_{50} \tag{5}$$

where  $K_{\rm T}$  is Shield's constant. The value of  $K_{\rm T}$  may range from about 0.027 to 0.06 depending on flow conditions and definition of incipient motion.

10. At incipient motion  $\bar{\tau}_0 = \tau_c$ . The OTFL (Equation 6) and MTFL (Equation 7) methods can then be derived as

$$\frac{\rho v^2}{(\gamma_s - \gamma) d_{50}} = K_T \left[ 5.75 \log_{10} \left( \frac{12.2 \text{pD}}{\text{md}_{50}} \right) \right]^2$$
 (6)

and

$$\frac{\rho v^2}{(\gamma_s - \gamma) d_{50}} = K_T \left\{ 5.75 \log_{10} \left[ \frac{12.2p}{m} \left( \frac{D}{d_{50}} + 1 \right) \right] \right\}^2$$
 (7)

#### Tractive force-power profile

11. A power formula for  $\tau_0$  can be formed which closely approximates the logarithmic equation over the range  $3 \le R/k_S \le 500$ . It was shown (Reese 1984) that this equation actually fit available data better than the logarithmic profile and could be solved directly, whereas the logarithmic

equation requires an iterative procedure. The power form of  $\bar{\tau}_{o}$  is

$$\bar{\tau}_{o} = \frac{\rho V^{2}}{63.39 \left(\frac{pD}{md_{50}}\right)^{1/3}}$$
 (8)

12. Combined with Equation 5, the final dimensionless form is

$$\frac{\rho V^2}{(\gamma_s - \gamma) d_{50}} = 63.39 K_T \left(\frac{pD}{md_{50}}\right)^{1/3}$$
 (9)

#### Froude number method

13. The Froude number method is commonly expressed as

$$\frac{d_{50}}{D} = K_F F^3 \tag{10}$$

where

 $K_F = empirical constant$ 

 $F = flow Froude number (V/\sqrt{gD})$  where g = acceleration of gravity)

14. When this method is used, great reliance is placed on model studies and field experience for the determination of  $\rm K_F$ . It is often used in areas of high or uncertain turbulence and in areas where flow configuration is controlled by a rapidly changing boundary (e.g., below structures).  $\rm K_F$  ranges from 0.22 for incipient motion in flume studies, to 0.35 for channel design, to as high as 7.5 for low-head navigation structures where energy dissipation is poor (Maynord 1978; Grace, Calhoun, and Brown 1973). A value of 1.0 is recommended for structures with effective energy dissipation.

15. Equation 9 can be rearranged as

$$\left[\frac{\gamma_{\rm m}^{1/3}}{(\gamma_{\rm s} - \gamma)63.39K_{\rm T}p^{1/3}}\right]^{3/2} \left[\frac{v}{(gD)^{1/2}}\right]^3 = \frac{d_{50}}{D}$$
 (11)

This is the same form as Equation 10.  $K_{\overline{F}}$  is equivalent to the left-hand term. Thus the Froude method can be thought of as a simplified tractive

force-power (TFP) profile. What is gained in simplicity of expression is lost in flexibility of input.

16. K is then

$$K_{F} = \left[ \frac{\gamma m^{1/3}}{(\gamma_{s} - \gamma)63.39 K_{T}^{-1/3}} \right]^{3/2}$$
 (12)

Solving for  $K_{\overline{T}}$  with  $\gamma_s$  = 165 lb/cu ft\* and  $\gamma$  = 62.4 lb/cu ft gives

$$K_{\rm T} = \frac{1}{104.23K_{\rm F}^{2/3}} \left(\frac{m}{p}\right)^{1/3} \tag{13}$$

Substitution into Equation 9 gives the appropriate dimensionless form:

$$\frac{\rho v^2}{(\gamma_s - \gamma)d_{50}} = \frac{1}{1.65K_F^{2/3}} \left(\frac{D}{d_{50}}\right)^{1/3}$$
 (14)

 $\boldsymbol{K}_{\overline{\boldsymbol{F}}}$  intrinsically incorporates the p and m adjustments. Method summary

17. The five equations for riprap design are then (using  $V = U_h$ ):

Isbash: 
$$\frac{\rho v^2}{(\gamma_s - \gamma)d_{50}} = 2\kappa_I^2$$
 (1)

OTFL: 
$$\frac{\rho v^2}{(\gamma_s - \gamma)d_{50}} = K_T \left[ 5.75 \log_{10} \left( \frac{12.2 \text{pD}}{\text{md}_{50}} \right) \right]^2$$
 (6)

$$\underline{\text{MTFL:}} \qquad \frac{\rho V^2}{(\gamma_s - \gamma)d_{50}} = K_T \left\{ 5.75 \log_{10} \left[ \frac{12.2p}{m} \left( \frac{D}{d_{50}} + 1 \right) \right] \right\}^2 \tag{7}$$

<sup>\*</sup> A table of factors for converting non-SI units of measurement to SI (metric) units is found on page 3.

$$\frac{\text{pV}^2}{(\gamma_s - \gamma)d_{50}} = 63.39 K_T \left(\frac{\text{pD}}{\text{md}_{50}}\right)^{1/3}$$
 (9)

Froude: 
$$\frac{\rho V^2}{(\gamma_s - \gamma)d_{50}} = \frac{1}{1.65K_F^{2/3}} \left(\frac{D}{d_{50}}\right)^{1/3}$$
 (14)

#### PART II: SOME RIPRAP DESIGN CONSIDERATIONS

18. In the design of riprap stone size, any of three flow situations or types may predominate. Depending on the situation, a slightly different design method is used. The three types are (a) upstream roughness dependence (Type I), (b) riprap roughness dependence (Type II), and (c) boundary geometry dependence (Type III).

#### Type I

19. In a Type I situation, flow moves from an upstream channel reach of lesser roughness into the riprap-protected reach. An example might be transition from a concrete-lined section to a riprap-protected section. If the upstream roughness is greater than that of the riprap, Type II methods should be used. It can be shown that if the riprap protrudes above the upstream bed by more than a small amount or if the roughness difference is great, there will be a transition section in which the forces attempting to dislodge the stone will be greater than further downstream where the velocity at the top of the level of the rock has been slowed. In Type I flow, the velocity of the upstream reach should be used to size the stone in this transition section. In many cases the velocity entering the section is sufficiently close to the eventual velocity within the section that Types I and II riprap design method will yield approximately equal  $d_{50}$  sizes. If the length of the transition section is assumed equal to the distance required to submerse the stone in a turbulent boundary layer initiated at the upstream edge of the riprap section, the transition section length can be estimated to be 75 to 100 times  $d_{50}$  .

#### Type II

SERVICE CONTRACTOR OF SERVICE CONTRACTOR OF SERVICE OF

20. Type II flow is used if upstream and protected section roughness are somewhat similar and riprap does not greatly protrude into the flow (thus creating a smooth transition), or for protected sections downstream from a transitional section when the velocity in the channel and the size of stone are interdependent. In this case an iterative solution is required. A size is first chosen and velocity calculated. Then this velocity is used to determine a stable riprap size. The initial and calculated sizes are compared and

the procedure repeated until approximate agreement is reached.

المحدد ومدحد

possessed interesting accessors anadous discussion broospesses

#### Type III

21. In Type III flow, the velocity distribution is largely determined by the boundary geometry. Turbulence caused by, for example, expansions, contractions, drops, or sills predominates. In these cases the refinements of velocity profile are overshadowed by boundary-generated macroturbulence. A judicious choice of empirical constant is then the most important factor in stone sizing. The Froude or Isbash methods are usually used in Type III situations because of their simplicity. Often model studies are recommended if the flow conditions are unique and the importance of the structure warrants the added cost.

#### Strip Sections

- 22. Often the channel perimeter is not uniformly protected. The banks may be protected and the bed left in its natural or excavated state. If a large side slope is to be protected, the riprap size may be decreased in longitudinal strips up the bank as a cost-saving measure.
- 23. Although the actual scour mechanism is not well understood in these cases, the toe of the bank or the lower portion of the riprap strip is usually most vulnerable to scour or stone displacement. Some methods for toe protection are discussed in Engineer Manual 1110-2-1601 (OCE 1970). Actual required toe depth is quite variable and depends on stream type, flow angle, bed and bank material, and history. It is sometimes calculated to be the sum of general and local scour plus one-half the anticipated bed form height.
- 24. The normal method of approach (short of two-dimensional mathematical modeling but beyond simply using mean channel velocity) when roughness varies in longitudinal strips is first to calculate the mean velocity in each strip (e.g., using a suitable backwater program for gradually varied flow or the alpha method (OCE 1970) for uniform flow). It is then assumed that the faster velocity of an adjacent strip impinges on a section of slower velocity at unknown and varying points. For example, the faster velocity in the center portion of a channel with protected banks is used to size the riprap on the bank, or the faster velocity on a lower portion of a bank is used to size the

riprap on an adjacent upper portion of the bank. These methods are illustrated in Table 1.

25. The built-in safety factor incurred by using this method will, for steeper slopes and shallower flows, give unrealistically large riprap sizes. For certain combinations of variables no solution can be found for the logarithmic methods. It is probably best, in these situations, to reconsider whether riprap is an appropriate form of bed or bank protection and, if it is, to choose a size based on experience or velocity measurement.

#### PART III: THE NOMOGRAPHIC METHOD

#### Basis of the Nomographic Method

26. The Nomographic Method is an attempt to provide a simple-to-use yet accurate method for riprap sizing. It has an additional advantage in that it also provides a design engineer with a visual "feel" for the relative sensitivity of various assumptions and placement situations used in design.

STATES THE STATES OF THE STATE

- 27. The basic concept of this method is illustrated by Plate 1. For a given set of conditions, a velocity versus depth plot can be drawn using a family of  $d_{50}$  curves. The designer simply finds the intersection of known velocity and depth and reads the appropriate  $d_{50}$  size directly. Plate 1 uses the OTFL equation (Equation 6) for a stated set of "base conditions." The problem is that there is an infinite number of combinations of conditions each of which would generate a different family of curves. For example, if the riprap is placed on a side slope, the family of curves would shift to the left, requiring a larger  $d_{50}$  size for the same velocity and depth.
- 28. Rather than shifting the  $d_{50}$  curves to the left (or right) when departures from base conditions are encountered, in the nomographic method, the velocity is shifted. The question can be asked, "What velocity would result in the same  $d_{50}$  size using the base condition family of curves (Plate 1 here) as would be obtained by plotting a new family of curves for the new set of conditions?"
- 29. A departure from any of the base conditions (Plates 1-5) is accounted for by an adjustment to the real-world velocity, creating a fictitious velocity. That is, any factor which increases or decreases the ability of a stone to remain stationary can be reflected by a corresponding decrease or increase in velocity. This fictitious new velocity is called the "effective velocity." Thus, through coefficients obtained from Plates 6-13, the user moves either to the right or left of the actual velocity on the velocity scale and then moves upward to the calculated depth and reads the d<sub>50</sub> size.
- 30. The base conditions (Plates 1-5) can be adjusted for riprap shape, side slope or bend placement, specific weight changes, use of different constant values or safety factors, use of hydraulic radius (channel shape), and use of different equivalent sand grain roughnesses. Examples in Table 1 illustrate adjustments to the base conditions. The following base conditions

are used in Plates 1-5: moderately angular riprap placed on the bed of a straight channel,  $\gamma_s$  = 165 lb/cu ft ,  $k_s$  =  $d_{50}$  , D is used instead of R , and base values for the constants are used ( $K_T$  = 0.04 ,  $K_F$  = 0.22 ,  $K_I$  = 1.2 ).

31. The tractive stress displacement methods depend on an accurate description of the vertical velocity profile to be able to transpose a known velocity to a bed shear stress. When the bed roughness elements are large in relation to the flow depth (between 1/10 to 1/3), the methods begin to lose accuracy due to roughness shape and free surface effects. These effects tend to increase the friction factor (slow the velocity) and thus lead to a more conservative design. The dashed lines on Plates 1-5 indicate a  $D/d_{50}$  value of 3 (roughness elements = 1/3 depth). These charts should not be used for design below this value as variation from profile assumptions reaches unacceptable levels.

#### Derivation

32. At incipient motion  $\bar{\tau}_0 = \tau_c$ . Several factors may increase actual shear  $(\bar{\tau}_0)$  or decrease critical shear  $(\tau_c)$ . Bend placement

33. The maximum shear in a bend (OCE 1970) can be expressed as

$$\tau_{b} = \overline{\tau}_{o} \left[ 3.12 \left( \frac{T}{R_{c}} \right)^{0.5} \right]$$
 (15)

where

 $\tau_h$  = shear in a bend

T = top width of channel entering bend

R<sub>c</sub> = centerline radius of curvature of bend

or

$$\tau_{\mathbf{b}} = \overline{\tau}_{\mathbf{c}} K_{\mathbf{B}} \tag{16}$$

where  $K_{\overline{B}}$ , the coefficient for bend shear, is the term in brackets in Equation 15.

#### Side slope placement

34. The required critical shear for side slope placement (OCE 1970) is expressed as

$$\tau_{s} = \tau_{c} \left[ \left( 1 - \frac{\sin^{2} \phi}{\sin^{2} \Theta} \right)^{1/2} \right]$$
 (17)

or

proposes appropriate proposes increases

$$\tau_{s} = \tau_{c} K_{s} \tag{18}$$

where

 $\tau_{\rm g}$  = side slope critical shear

 $\phi$  = side slope angle

 $\Theta$  = riprap angle of repose

 $K_s$  = coefficient of side slope shear (bracketed term in Equation 17) Safety factor

35. The safety factor is expressed as

$$\tau_{SF} = \overline{\tau}_{O} K_{SF} \tag{19}$$

where

 $\tau_{\rm SF}$  = actual shear with a safety factor applied

K<sub>SF</sub> = safety factor

A factor of 1.5 had been recommended for moderate nonuniformity in plan, profile, or roughness (OCE 1971).

36. All of these factors can be applied independently (although the bend correction equation incorporates about a 1.5 safety factor with it when compared with straight channel design) at the discretion of the designer. Thus

$$\bar{\tau}_{o} K_{B} K_{SF} = \tau_{c} K_{s}$$
 (20)

or

$$\bar{\tau}_{o} = \frac{K_{s}}{K_{B}K_{SF}} \tau_{c}$$
 (21)

#### Power Profile

37. Remembering that  $k_s = md_{50}$  and R = pD and using  $\gamma_s'$  to represent a specific weight of stone other than 165 lb/cu ft (base condition), Equations 5 and 8 are substituted into 21 for  $\bar{\tau}_o$  and  $\tau_c$ , respectively, and rearranged to give

$$V = \left[ \frac{63.39 K_{T}^{"} (\gamma_{s}^{"} - \gamma) d_{50}^{"} K_{s}}{K_{B}^{\rho}} \right]^{1/2} \left( \frac{pD}{md_{50}} \right)^{1/6}$$
 (22)

where  $K_T^{\prime}$  is the use of a constant other than the base constant.  $K_T^{\prime}$  combines  $K_T$  and  $K_{SF}$  such that  $K_T^{\prime} = K_T^{\prime}/K_{SF}$ . Thus a choice of  $K_T^{\prime}$  of 0.027 is equivalent to a shear safety factor of 1.5 (0.027 = 0.04/1.5) and so on.

38. The variable V in Equation 22 is the actual velocity. The effective velocity is that which will give the same  $\,\mathrm{d}_{50}\,$  for the same depth but for base conditions. It is expressed as

$$V_{eff} = \left[\frac{63.39K_{T}(\gamma_{s} - \gamma)d_{50}}{\rho}\right]^{1/2} \left(\frac{D}{d_{50}}\right)^{1/6}$$
 (23)

where the base value for  $K_T$  is 0.04 and  $\gamma_s$  is 165 lb/cu ft.

39. Dividing Equation 23 by 22 gives

$$\frac{V_{eff}}{V} = \left(\frac{0.04}{K_T^{\dagger}}\right)^{1/2} \left[\frac{102.6}{(\gamma_s^{\dagger} - \gamma)}\right]^{1/2} \left(\frac{K_B}{K_s}\right)^{1/2} \left(\frac{m}{p}\right)^{1/6}$$
(24)

or

$$V_{eff} = C_{t} C_{g} C_{b} C_{s} C_{m} C_{p} V$$
 (25)

where

$$C_{t} = \left(\frac{0.04}{K_{T}^{\dagger}}\right)^{1/2}$$

$$C_{g} = \left[\frac{102.6}{(\gamma_{g}^{v} - \gamma)}\right]^{1/2}$$

$$c_b = \kappa_B^{1/2}$$

$$C_{s} = \left(\frac{1}{K_{s}}\right)^{1/2}$$

$$C_{\rm m} = {\rm m}^{1/6}$$

$$C_p = \left(\frac{1}{p}\right)^{1/6}$$

Thus for any given set of conditions the user determines the correction coefficients and multiplies them times the given velocity to obtain an effective velocity. He then reads the  $\,\mathrm{d}_{50}\,$  size directly from the intersection point of effective velocity and depth.

#### Froude and Isbash Methods

40. Because of the nature of the Froude and Isbash methods, the  $^{\rm C}_{\rm p}$  and  $^{\rm C}_{\rm m}$  corrections are not applicable to them. Side slope and bend corrections are not applicable to the Isbash method in its original derivation.

#### Logarithmic Profile

41. The logarithmic profile can be arranged similar to the power profile giving

$$V = 5.75 \left[ \frac{K_s K_T' (\gamma_s' - \gamma) d_{50}}{K_B \rho} \right]^{1/2} \left[ \log_{10} \left( \frac{12.2 \text{pD}}{\text{md}_{50}} \right) \right]$$
 (26)

and

$$v_{eff} = 5.75 \left[ \frac{K_T(\gamma_s - \gamma) d_{50}}{\rho} \right]^{1/2} \left[ log_{10} \left( \frac{12.2D}{d_{50}} \right) \right]$$
 (27)

Dividing Equation 27 by Equation 26 gives

$$\frac{V_{eff}}{V} = \left(\frac{0.04}{K_T^{\dagger}}\right)^{1/2} \quad \left[\frac{(102.6)}{\gamma_s^{\dagger} - \gamma}\right]^{1/2} \quad \left(\frac{K_B}{K_S}\right)^{1/2} \quad \left[\frac{\log_{10}\left(\frac{12.2D}{d_{50}}\right)}{\log_{10}\left(\frac{12.2pD}{md_{50}}\right)}\right] \tag{28}$$

or

HE ESSAND MATERIAL PROCESSION OF SAME PROPERTY CONTINUES PROCESSOR

$$V_{eff} = C_t C_g C_b C_s C V$$
 (29)

where  $\mathbf{C}_{\mathbf{t}}$  ,  $\mathbf{C}_{\mathbf{g}}$  ,  $\mathbf{C}_{\mathbf{b}}$  , and  $\mathbf{C}_{\mathbf{s}}$  are as defined following Equation 25 and

$$C = \frac{\log_{10} \left(\frac{12.2D}{d_{50}}\right)}{\log_{10} \left(\frac{12.2pD}{md_{50}}\right)}$$
(30)

C carries with it the correction for both hydraulic radius and equivalent roughness and was arranged in this way to provide multiplicative rather than additive corrections. For local velocity use set R = D (the extreme top of the chart).

#### Summary

42. The various coefficients used to adjust the actual velocity can now

be summarized. These equations may be used in lieu of the plates if greater accuracy is desired.

a. Stone shape and side slope placement C corrections are found in Plates 6 and 7, respectively, and expressed as

$$C_{s} = \left(1 - \frac{\sin^{2} \phi}{\sin^{2} \theta}\right)^{-1/4} \tag{31}$$

Plate 6 was developed from work by Simons (1957) and is used to estimate angle of repose.

b. The bend correction, found in Plate 8, is expressed as

$$C_b = 1.77 \left(\frac{T}{R_c}\right)^{1/4} \tag{32}$$

c. The specific weight correction is found from Plate 9 and expressed as

$$c_{\mathbf{g}} = \left[ \frac{102.6}{(\gamma_{\mathbf{g}}^{\dagger} - 62.4)} \right]^{1/2} \tag{33}$$

d. The constant correction coefficient for each of the four methods is found in Plate 10. For the power and logarithmic profiles it is given as

$$C_{t} = \left(\frac{0.04}{K_{T}^{\dagger}}\right)^{1/2} \tag{34}$$

For the Isbash method it is

TEST STATES TO SECOND TO SECOND SECON

$$C_{i} = \frac{1.2}{K_{I}^{\dagger}} \tag{35}$$

where  $\ensuremath{\mbox{K}}_{\ensuremath{\mbox{\scriptsize I}}}^{\mbox{\tiny "}}$  is the chosen Isbash constant. For the Froude method it is

$$c_{f} = \left(\frac{K_{F}^{\prime}}{0.22}\right)^{1/3} \tag{36}$$

where  $K_F^{\bullet}$  is the chosen Froude constant.

e. The channel shape correction factor for the power profile is found in Plate 11 for a known top width, depth, and side slope. It is given as

$$C_{p} = \left(\frac{1}{p}\right)^{1/6} \tag{37}$$

f. The correction for both shape of channel and equivalent roughness for the logarithmic profiles is given in Plate 12 and as

$$C = \frac{\log_{10} \left(\frac{12.2D}{d_{50}}\right)}{\log_{10} \left(\frac{12.2pD}{md_{50}}\right)}$$
(38)

The depth used here depends on which logarithmic method will be used. The OTFL method uses depth to top of rock while the MTFL method uses depth to  $d_{50}$  below top of rock. Therefore use  $D/d_{50}+1$  in place of  $D/d_{50}$  in both numerator and denominator of Equation 38 for the MTFL method.

g. Plate 13 gives the power profile correction for equivalent roughness as

$$C_m = m^{1/6}$$
 (39)

#### Safety Factors

THE PERSONAL PROPERTY PROPERTY TO SERVICE ASSESSED TO SERVICE SERVICE SERVICE TO SERVICE SERVICE SERVICE SERVICE SERVICE SERVICE SERVICE SERVIC

43. Safety factors (OCE 1971) for the logarithmic and power profiles are found from

$$SF_{T} = \frac{0.04}{K_{T}^{\dagger}} \tag{40}$$

where  $SF_T$  is the shear safety factor. For the Froude method, assuming 0.22 to be the ideal situation incipient motion constant, it is found that

$$SF_{F} = \left(\frac{K_{F}^{\dagger}}{0.22}\right)^{2/3} \tag{41}$$

These are shear safety factors. For example: to provide the recommended 1.5 safety factor on the calculated actual shear,  $K_{\overline{T}}'$  must be 0.027 and  $K_{\overline{F}}'$  must be 0.404.

#### Shear Analysis

- 44. Insight can be gained by returning to the original premise for shear-induced riprap instability of paragraph 10. At incipient motion the shear acting on a stone equals the critical shear for movement or  $\bar{\tau}_0 = \tau_c$ . Equation 20 demonstrated in a preliminary way the relationship between the actual and critical shears  $\bar{\tau}_0$  and  $\bar{\tau}_c$ , and the various factors affecting them. By combining Equations 31-38 (the factors read directly from the nomograph) with the definitions for the shears, a nomographic shear analysis can be performed, identical to the method given in EM 1110-2-1601 (OCE 1970).
  - 45. For the OTFL method the proper equation is

$$\frac{\gamma v^2}{\left(32.6 \log_{10} \frac{12.2D}{d_{50}}\right)^2} \left(C_b C_t C\right)^2 = 4.10 d_{50} \left(\frac{1}{C_s C_g}\right)^2$$
(42)

Here, and in the two equations following, the form of the equation is

$$\bar{\tau}_{o}^{eff}$$
  $eff$  (43)

The left side is the actual shear adjusted for channel shape, bend, equivalent roughness, and safety factor. The right side of the equation is the critical shear adjusted for specific weight and side slope placement.

46. The equation for the MTFL method is

$$\frac{\gamma v^2}{\left\{32.6 \log_{10} \left[12.2 \left(\frac{D}{d_{50}} + 1\right)\right]\right\}^2} \left(C_b C_t C\right)^2 = 4.10 d_{50} \left(\frac{1}{C_s C_g}\right)^2$$
(44)

47. The equation for the power profile method is

$$\frac{\gamma V^2}{63.69 g \left(\frac{D}{d_{50}}\right)^{1/3}} \left(C_b C_t C_p C_m\right)^2 = 4.10 d_{50} \left(\frac{1}{C_s C_g}\right)^2$$
(45)

#### Computer Programs

48. A computer program which allows for on-line, interactive riprap design using the methods presented in this paper is available at all US Army Corps of Engineers design offices through the Conversationally-Oriented Real-Time Programming System (CORPS). It is entitled H7011-Riprap Design by Four Methods. For complete documentation and information, contact the Engineer Computer Programs Library (WESIM-SC) at FTS 542-2581.

#### Example 1: Type I Flow--Bend Placement

Given:

$$R_c = 200 \text{ ft}$$

$$D = 8 ft$$

$$k_s \approx 2d_{50}$$

$$T = 50 ft$$

Side Slope = 2H:1V

Moderately rounded stone, trapezoidal channel

Use TFP method and mean channel velocity (upstream)

Step 1. Side Slope Correction

Assume 
$$d_{50} = 15$$
 in.  $\phi = 26.6$  deg  $K_T^{\dagger} = 0.027$  (1.5 safety factor)

From Plate 6:  $\Theta = 40.5 \text{ deg}$ 

From Plate 7: 
$$C_g = 1.17$$

Step 2. Bend Correction

$$T/R_c = 50/200 = 0.25$$

From Plate 8: 
$$C_b = 1.25$$

Step 3. Specific Weight Correction

From Plate 9: 
$$C_g = 0.95$$

Step 4. Power Profile Channel Shape Correction

$$T/D = 50/8 = 6.25$$

From Plate 11: 
$$C_p = 1.07$$

Step 5. Equivalent Sand Grain Roughness Correction, Power Profile

$$m = 2$$

From Plate 13: 
$$C_m = 1.12$$

Step 6. Safety Factor

$$K_{T}^{*} = 0.027$$

(Continued)

From Plate 10:  $C_r = 1.22$ 

Step 7. Power Profile

$$V_{eff} = C_s C_b C_g C_p C_m C_t V$$
  
= (1.17)(1.25)(0.95)(1.07)(1.12)(1.22)(11)  
= 22.34 fps

From Plate 4:  $d_{50} = 31$  in.

Step 8. Check Side Slope Correction

$$d_{50} = 31 \text{ in.}$$
  $\phi = 26.6 \text{ deg}$   $K_T^* = 0.027$ 

From Plate 6:  $\Theta = 41.0 \text{ deg}$ 

From Plate 7:  $C_s = 1.17$ 

The side slope correction does not change so the rock size  $d_{50}$  = 31 in. is correct.

#### Example 2: Type I Flow--Transition Design

Given: Q = 4,000 cfs Bottom width = 50 ft 
$$\gamma_s$$
 = 165 lb/cu ft

A. Concrete Section

THE PROPERTY OF SESTIONS OF THE PROPERTY. STREET, STRE

Manning's 
$$n = 0.012$$
 V (mean) = 10.75 fps

$$D = 6 \text{ ft}$$
 V (center) = 11.69 fps

$$V (sides) = 6.84 fps$$

B. Transition Section

Assume a fairly smooth transition

Power method 
$$k_s = 3d_{50}$$
  $K_T^{\dagger} = 0.027$  (1.5 safety factor)

Step 1. Side Slope Correction

Assuming 
$$d_{50} = 24$$
 in.

(Continued)

From Plate 6:  $\theta = 41.5 \text{ deg (moderately angular stone)}$ 

From Plate 7:  $C_g = 1.16$ 

Step 2. Safety Factor

From Plate 10:  $C_{+} = 1.22$ 

Step 3.  $k_s = 3d_{50}$ 

From Plate 13:  $C_m = 1.20$ 

Step 4.  $V_{eff} = V(C_s)(C_t)(C_m) = (11.69)(1.16)(1.22)(1.20) = 19.85 \text{ fps}$ 

From Plate 4:  $d_{50} = 25$  in.

Step 5. Assume approximate transition zone distance of  $75d_{50} = 150 \text{ ft}$ .

C. Downstream Section Size Check

Assume n = 0.030 (conservative)

Then V (center) = 6.54 fps V (mean) = 5.77 fps

 $D = 9.93 \, ft$ 

 $d_{50} = 3.5 in.$ 

D. The designer now has the choice of how to step down the size from 24 in. to an unprotected section. The 24-in. size will be carried 100 ft downstream with a 12-in. stepdown for an additional 50 ft with tie-ins.

#### Example 3: Type II Flow--Side Slope Placement

Given: Q = 8,000 cfs

Bottom width = 70 ft

2H:1V side slopes

Bottom slope = 0.0040

Bottom roughness: Manning's n = 0.028

 $\gamma_c = 165 \text{ lb/cu ft (moderately angular stone)}$ 

Assume uniform flow

 $k_s = 2d_{50}$ 

1.5 safety factor

(Continued)

Size stone for bank protection using power profile method and sectional velocities.

Step 1. Determine applicable velocities and depth. Using CORPS program H7012 - The Alpha Method:

Assuming Manning's  $n = 0.04d_{50}^{1/6}$  (d<sub>50</sub> in feet) and d<sub>50</sub> = 12 in.

Manning's n = 0.04 on protected slopes

Center velocity = 13.28 fps

Depth = 7.88 ft

Side slope velocity = 5.44 fps

Step 2. Side slope correction

From Plate 6: Repose angle = 41 deg

From Plate 7:  $C_s = 1.17$ 

Step 3. Equivalent roughness correction

From Plate 13 (m = 2):  $C_m = 1.12$ 

Step 4. Safety factor correction

From Equation 40 for  $SF_T = 1.5$ :  $K_T^{\dagger} = 0.027$ 

From Plate 10:  $C_r = 1.22$ 

Step 5.  $V_{eff} = (1.17)(1.12)(1.22)(13.28) = 21.32$  fps

From Plate 4:  $d_{50} = 26$  in.

Step 6. Recalculate downstream velocity using larger  $d_{50}$  size

Manning's  $n = 0.04(26/12)^{1/6} = 0.045$ 

Using H7012

Velocity center = 13.33 fps

Velocity bank = 4.85 fps

Depth = 7.92 ft

(Continued)

(Sheet 4 of 5)

Step 7. Recalculate 
$$d_{50}$$
 size

$$V_{eff} = (1.17)(1.12)(1.22)(13.33) = 21.31 \text{ fps}$$

From Plate 4: 
$$d_{50} = 27$$
 in. (OK)

#### Example 4: Type III Flow--Basin Design

Flow below drop structure. Use Isbash and Froude methods.

V (over end sill) = 12.4 fps

$$D = 11 ft$$

 $\gamma = 185 \text{ lb/cu ft}$ 

3H:1V side slopes with moderately angular stone

 $K_{T}^{\bullet}$  and  $K_{F}^{\bullet}$  are selected based on experience

Step 1. Specific weight correction

From Plate 9:  $C_g = 0.91$ 

Step 2. Side slope correction (Froude only)

From Plate 6:  $\theta = 41.5 \text{ deg}$ 

From Plate 7:  $C_s = 1.07$ 

Step 3. From Plate 10:  $C_i = 1.39$  for  $K_I' = 0.86$  (for high-turbulence

location)

 $C_f = 1.65$  for  $K_F^{\dagger} = 1.00$  (for structures with

effective energy dissipation)

Step 4. Isbash

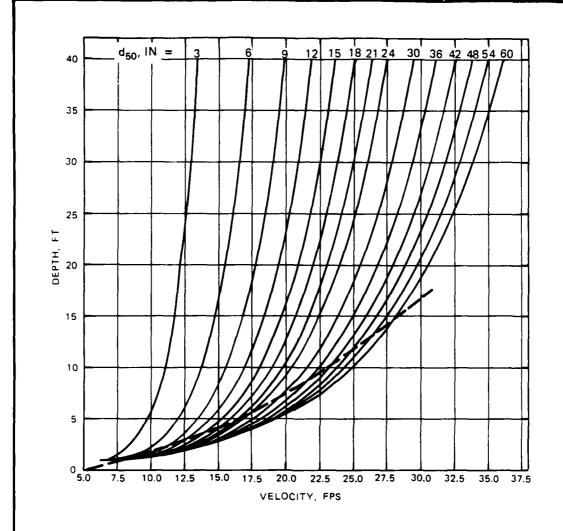

$$v_{eff} = v_{g}^{c} c_{i} = (12.4)(0.91)(1.39) = 15.68 \text{ fps}$$

$$d_{50} = 20 \text{ in.}$$

Froude

$$V_{eff} = VC_gC_fC_s = (12.4)(0.91)(1.65)(1.07) = 19.92 \text{ fps}$$

$$d_{50} = 36 \text{ in.}$$

$$\frac{\rho V^2}{(\gamma_s - \gamma)d_{50}} = K_t \left[ 5.75 \text{ LOG } (\frac{12.2 \text{ D}}{k_s}) \right]^2$$
